Elbow fractures are among the most common traumatic problems in the pediatric population and consist of approximately 15% of all pediatric fractures. In some studies, the cause of 85% of orthopedic surgeries is elbow fractures. These fractures can include supracondylar, lateral condyle, neck of radius, medial epicondyle, olecranon, head of radius, and intercondylar fractures.

Post-traumatic elbow stiffness in children is a common complication that can occur after elbow fractures. Anatomic reduction of displaced intra-articular elbow fractures is important to prevent post-traumatic arthritis as well as to maintain the precise anatomic relationships among the three bones that make up the elbow.

The University of Michigan is a leading provider in the treatment of elbow fractures from simple to complex. Our fellowship-trained orthopaedic surgeons specialize in hand, wrist, and elbow surgery. Our goal is to restore mobility and function of the elbow as soon as possible with minimal impact on the patient's quality of life.
Both acute and chronic fractures are then discussed in detail beginning with a brief outline of the epidemiology classification and work up of each fracture but the main focus will be on providing a master’s approach to the surgical treatment of these injuries including supracondylar fractures, capitellar shear fractures, elbow dislocations, Monteggia fracture dislocations, and cubitus varus and valgus among others.
